

MAISON — Product Discovery & Strategy

Your Personal AI Fashion House *From Inspiration to Outfit.*

Status: Discovery phase. Current focus is validating **desirability** (do people actually want this and will they change behavior for it) before investing in feasibility (AI/catalog engineering) or viability (business model).

1. Problem Discovery

The 5 Whys

Step	Question / Answer
Problem	People browse multiple websites to build one outfit.
Why?	No single website has everything they want.
Why?	Users don't want products — they want an outfit .
Why?	Shopping decisions are contextual ("I have a wedding," "I have an interview").
Why?	Fashion shopping is goal-oriented , but e-commerce is product-oriented . ✖

The Real Problem

Online shopping platforms are designed to sell individual products, while customers think in terms of complete looks, occasions, and personal style.

This breaks down into **four sub-problems**:

1. **Fragmented Discovery** — Pinterest → Google Lens → Myntra → Amazon → Ajio → H&M → Flipkart → still missing shoes. Too many tabs.
2. **Products don't understand context** — searching "white shirt" returns 1,000 shirts when the user meant "summer vacation outfit." Intent is lost.
3. **Users don't know styling** — "Does this shirt go with these pants?" has no answer on current platforms.
4. **Budget optimization is invisible** — the same outfit can be ₹2,500 cheaper elsewhere and the user never discovers it.

The hidden problem underneath all four: **decision fatigue**. Users spend more time deciding than buying.

2. Problem Statement

Consumers think in complete outfits, while e-commerce platforms are optimized for individual product discovery — creating unnecessary friction in outfit planning, product comparison, and purchase decisions.

Fashion shopping is fragmented, time-consuming, and mentally exhausting because users must manually discover, compare, style, and purchase complementary items across multiple platforms to create a single outfit.

3. Jobs To Be Done

Five distinct intents surfaced during discovery — each a candidate product direction:

1. "I have this picture. Help me buy the whole outfit."
2. "I have a budget of ₹5,000. Create an outfit."
3. "I have these shoes. Complete the rest."
4. "I have an interview tomorrow. Dress me."
5. "I'm travelling to Goa. Create outfits."

Chosen Beachhead

"I found an outfit I love on Instagram/Pinterest. Help me recreate it within my budget."

Selected because it is: immediately understandable, highly visual, naturally suited to AI, easy to explain/test, and sharply scoped. Occasion-based planning and wardrobe completion are natural next steps once this is validated.

Functional / Emotional / Social Jobs

Type	Job
Functional	Recreate or build a complete outfit for a specific occasion without manually searching across multiple platforms.
Emotional	Feel confident that I look good and made the right decision.
Social	Present myself confidently in social and professional settings.

4. Why This Problem Is Unsolved

Why hasn't Myntra solved this already?

	Myntra's Goal	Maison's Goal
Objective	Sell Myntra inventory	Help the user make the best decision
Scope	Inventory-led marketplace	Retailer-agnostic shopping assistant

Helping users compare across competitors *reduces* Myntra's own sales — a direct strategic conflict. This isn't a capability gap; it's an **incentive gap**, and it's the core defensibility argument for Maison: no inventory-holding retailer is structurally motivated to build this well.

5. Competitive Landscape

Direct Competitors — Fashion Retailers

Competitor	Strength	Weakness (for this use case)
Myntra	Large catalog, strong search	Product-first, limited to own inventory
Savana	Trend discovery, model-based outfit inspiration	Recommendations constrained to Savana's own catalog
Newme	Trend-driven, influencer appeal	Ecosystem remains brand-specific
H&M	Curated collections	Limited inventory vs. a marketplace
Zara	Premium styling/merchandising	Closed ecosystem, higher prices
Ajio	Large marketplace	Manual outfit assembly
Amazon Fashion	Huge selection	Weak styling experience

Indirect Competitors

- Inspiration platforms:** Pinterest, Instagram, YouTube, fashion influencers — where the journey begins, but not where it's completed.
- AI & search:** Google Lens, ChatGPT, in-app visual search — identify products but don't orchestrate the full buying journey.
- AI styling apps:** Style DNA (personal style profiles), DRESSX Agent (styling + try-on + shopping within partner ecosystem), SpreeAI (try-on + size recommendation for retailers).
- FindGPT** — closest analog: DM an Instagram outfit, AI finds similar products, suggests where to buy, can complete checkout. Core value prop is “*shop this outfit.*” Maison's is “*help me build the right outfit for my situation*” — a broader, context-driven job.

The Savana Deep-Dive

Savana already recommends matching products for a look — so the differentiator **cannot** be “nobody recommends matching products.” The real gap:

User: “Recreate this look under ₹4,000.” Savana: “Here's what we sell.” Maison: “Here's the best way to achieve this look, regardless of where each item comes from.”

Feature Comparison

Capability	Pinterest	Savana	Myntra	Google Lens	Maison
Outfit inspiration	✓	✓	△	✗	✓
Visual search	✗	✗	△	✓	✓
Complete outfit generation	✗	△	✗	✗	✓
Multi-retailer recommendations	✗	✗	✗	✗	✓
Budget optimization	✗	✗	△	✗	✓
Occasion-based planning	✗	△	△	✗	✓
AI styling assistant	✗	△	△	✗	✓

Academic / Research Landscape

Active research area: complete outfit recommendation, compatibility prediction, outfit generation, personalized fashion AI (e.g., DiFashion, OutfitGAN, TrendGen). The open-source/HuggingFace ecosystem (IDM-VTON, CLIP-based visual search, fashion embeddings) skews toward **virtual try-on and image similarity**, not end-to-end shopping assistance — validating that the problem is real, unsolved, and still evolving.

6. Positioning

Not: “AI outfit finder” **Instead:** “The first retailer-agnostic AI styling assistant.”

Unique positioning statement:

A context-aware AI fashion assistant that helps users recreate, personalize, and purchase complete outfits based on their style, budget, occasion, weather, body preferences, and real-time product availability across multiple retailers.

The moat is not AI search. It’s the combination of:

Personal Context + Fashion Knowledge + Budget Reasoning + Occasion Awareness + Weather + Wardrobe + Retail Intelligence

Very few products combine all of these into a single decision engine — this is best framed as an **AI Fashion Decision Platform**, not a search tool.

7. Target Audience & Personas

MVP Audience: Urban women aged 20–30 who frequently discover fashion inspiration on Pinterest or Instagram and experience decision fatigue while recreating complete outfits across multiple online retailers.

“Gen Z” is a demographic. “People trying to accomplish a job” is a target audience — the latter is what defines Maison’s user.)

Situation Prioritization

Situation	Pain Level	Frequency	Willingness to Use AI
Job interviews	★★★★★	Medium	Very High
Weddings	★★★★★	Medium	Very High
First dates	★★★★★	Medium	Very High
Vacations	★★★★	Medium	High
Parties	★★★★	Medium	High
Office	★★★	High	High
College	★★★	High	High
Festivals	★★★★	Low	High
Daily casual wear	★★	Very High	Medium

High-stakes, low-frequency occasions have the strongest pain and the highest willingness to use AI — a good signal for where to focus early acquisition.

Persona 1 — Riya Sharma, “The Inspiration-Driven Shopper” (Primary)

👤 Basic Information

--	--

Attribute	Details
Age	24
Occupation	Product Marketing Executive
Location	Bangalore
Income	₹9 LPA
Education	Bachelor's Degree
Relationship Status	Single
Tech Savviness	High
Shopping Frequency	2–4 times/month

About

Riya enjoys dressing well but doesn't enjoy the shopping *process* itself. She constantly discovers outfits through Pinterest, Instagram Reels, fashion influencers, and celebrity looks — but turning inspiration into a complete outfit becomes frustrating because she has to manually search for every item across multiple shopping platforms. She values convenience, aesthetics, and confidence more than brand loyalty.

Goals

Primary: - Recreate outfits she discovers online - Save time while shopping - Stay within budget - Build complete looks instead of buying isolated pieces - Look stylish without needing deep fashion knowledge

Secondary: - Discover new brands - Reduce shopping stress - Experiment with new styles confidently

Pain Points

- Searches across 5–6 apps for one outfit
- Gets overwhelmed by thousands of product options
- Doesn't know whether pieces match
- Frequently finds items out of stock in her size
- Unsure if she's overpaying
- Wonders whether there's a better alternative elsewhere

Motivations

- Wants to feel confident at social events
- Likes fashion but values convenience over browsing
- Enjoys discovering trends but dislikes assembling outfits manually
- Wants AI to simplify decision-making rather than replace her personal style

Shopping Behaviour

Discovers fashion on	Pinterest, Instagram, fashion creators, friends
Shops from	Savana, Myntra, Newme, H&M, Zara, Ajio
Before purchasing	Checks reviews, compares prices, searches alternatives, asks friends for opinions, saves products for later

Digital Behaviour

- Mobile-first user
- Active on Instagram daily
- Creates Pinterest boards
- Comfortable with AI-powered apps
- Shares screenshots with friends before buying

Frustration Quote

"I already know the look I want. I just don't want to spend an hour finding every single piece."

Jobs To Be Done

Type	Job
Functional	Help me recreate outfits from social media quickly.
Emotional	Help me feel confident that my outfit looks good.
Social	Help me express my style without spending hours shopping.

Success Criteria

For Riya, the product succeeds if: - She finds a complete outfit in under 5 minutes - The recommendations stay within her budget - She doesn't need to open multiple shopping apps

Persona 2 — Neha Verma, "The Busy Professional" (Primary)

Basic Information

Attribute	Details
Age	29
Occupation	Senior Consultant
Location	Gurgaon
Income	₹18 LPA
Education	MBA
Relationship Status	Married
Tech Savviness	High
Shopping Frequency	Once or twice a month

About

Neha works long hours and has very little time for shopping. She doesn't follow fashion influencers or trends closely, but she wants to look polished and appropriate for work, client meetings, vacations, weddings, and social events. Shopping feels like another task on an already full schedule.

Goals

Primary: - Find occasion-appropriate outfits quickly - Avoid making poor fashion choices - Buy complete outfits in one session - Spend less time browsing

Secondary: - Invest in versatile wardrobe pieces - Get reliable styling suggestions - Avoid impulse purchases

Pain Points

- Doesn't know what combinations work well
- Finds shopping mentally exhausting
- Gets distracted by too many options
- Doesn't have time to compare retailers
- Often postpones shopping until the last minute
- Worries about dressing appropriately for different occasions

Motivations

- Wants to save time
- Values convenience over endless browsing

- Wants recommendations she can trust
- Prefers fewer but higher-quality choices
- Seeks confidence rather than fashion experimentation

 Shopping Behaviour

Shops from	Myntra, Zara, H&M, Amazon Fashion
Typically shops for	Office wear, business travel, weddings, vacations

 Digital Behaviour

- Shops mostly on weekends
- Uses Google search more than Pinterest
- Reads reviews carefully
- Often purchases from saved wishlists

 Frustration Quote

“Don’t show me 500 dresses. Show me three complete outfits that are perfect for my event.”

 Jobs To Be Done

Type	Job
Functional	Help me choose an outfit suitable for my occasion without comparing dozens of products.
Emotional	Reduce the anxiety of making the wrong fashion decision.
Social	Help me present myself confidently in professional and social settings.

 Success Criteria

For Neha, the product succeeds if: - She completes outfit planning in one session - She trusts the recommendations without needing extensive comparison - She feels prepared for the occasion

 Why These Two Personas

They represent two distinct jobs-to-be-done, not just two age groups:

	Riya	Neha
Core job	“Recreate the look I discovered.”	“Help me decide what to wear.”
Product focus	Image search, trend matching, recreation, budget optimization	Occasion planning, confidence, speed, curation

These are two distinct JTBDs, not two age brackets — they will pull the roadmap in different directions and should be tracked separately during validation. Riya’s flow leans on image input and trend-matching; Neha’s leans on structured prompts (occasion + budget) and speed. If validation shows one persona responds far more strongly than the other, that should directly inform which input mode (image vs. text) gets prioritized for the MVP build.

8. Value Proposition Canvas

Customer Pains (prioritized)

Pain	Severity
Searching across multiple apps	 Critical

Decision fatigue	● Critical
Difficulty styling outfits	● Critical
Too many choices	● Critical
Finding matching accessories	⊗ High
Out-of-stock sizes	⊗ High
Budget mismatch	⊗ High
Fear of buying the wrong outfit	⊗ High
Weather/occasion mismatch	● Medium
Inconsistent recommendations	● Medium

Pain Relievers → Gain Creators

Customer Pain	Maison's Response
Too many websites	Search once, get aggregated outfit recommendations
Decision fatigue	Present 2–3 curated outfits instead of hundreds of products
Styling uncertainty	AI generates coordinated outfits, not isolated items
Out-of-stock sizes	Suggest visually similar in-stock alternatives
Budget constraints	Build outfits that fit a stated budget
Manual comparison	AI compares relevant products and trade-offs

The core insight: most shopping apps optimize for *Product Discovery*. Maison should optimize for **Decision Confidence**. That's the shift the entire product is built around.

9. User Research

(Planned/simulated methodology for this stage — to be replaced with real interview data as research is conducted.)

Objective: Understand how urban young professionals discover, evaluate, and purchase fashion online, and identify the biggest friction points in creating complete outfits for different occasions.

Participants: 15, ages 20–30, Bangalore/Delhi/Mumbai/Pune, frequent users of Pinterest, Instagram, Myntra, Savana, Newme.

Methods: Semi-structured interviews, shopping journey mapping, competitive walkthroughs, affinity mapping.

Key Insights

#	Insight	Confidence
1	Users shop for outcomes, not products ("I have a wedding," not "I need a white shirt")	★★★★★
2	Inspiration and purchase happen on different platforms — users manually bridge the gap	★★★★★
3	Shopping is fragmented across 5–7 apps for one outfit	★★★★★
4	Decision fatigue matters more than search difficulty	★★★★★
5	Users prefer complete-look recommendations over single products	—

6	Budget is flexible; confidence is not — “if I know this outfit looks good, I’m okay spending more”	—
7	The same item is styled differently by weather/occasion/destination	—
8	Users seek external validation (share screenshots with friends before buying)	—
9	Users want fewer, better recommendations (3 curated > 300 products)	—
10	Size unavailability forces users to restart their entire search	—

Affinity Map

Theme	Insight
Discovery	Users begin with inspiration, not product search
Decision Making	Decision fatigue is a bigger pain than product discovery
Personalization	Recommendations must match occasion, weather, budget, style
Shopping Behaviour	Users compare multiple retailers before buying
Confidence	Validation is more valuable than endless choice

10. Design Principles

- 1. **Design around occasions, not categories.** Users think “wedding,” not “blue dress.”
- 2. **Recommend complete outfits, not individual products.** Solve the end goal, not a single shopping task.
- 3. **Reduce cognitive load.** Fewer, better recommendations beat endless scrolling.
- 4. **Use context to personalize every recommendation** — budget, weather, occasion, wardrobe, style.
- 5. **Build trust before optimizing for conversion.** Confidence precedes purchase.

Foundational insight: Users don’t want AI to choose their style. They want AI to eliminate the repetitive work of searching, comparing, matching, and evaluating — while the final decision stays theirs.

Maison isn’t replacing personal taste. It’s acting like an experienced stylist who lays out a few thoughtfully curated options and says: “Here are three outfits that fit your style, budget, and occasion. Which one feels most like you?”

11. Vision, Mission & Core Hypothesis

Vision: To become the world’s most trusted AI fashion companion, empowering people to express themselves confidently through personalized style.

Mission: Transform fashion inspiration into complete, personalized outfits by combining AI, contextual understanding, and intelligent product discovery.

Core insight: People don’t struggle to buy clothes. They struggle to make confident fashion decisions.

Primary Hypothesis

If users receive 2–3 complete, personalized outfit recommendations based on an image or text prompt, they will make purchase decisions faster and with greater confidence than when manually browsing multiple shopping platforms.

Formal (If/Then/Because):

We believe young professionals who shop for occasion-based outfits experience high decision fatigue during outfit planning. **If** Maison provides 2–3 curated, personalized outfit recommendations based on an inspiration image or text prompt, **then** users will complete outfit selection faster and report higher confidence than with their existing process, **because** AI removes the repetitive work of searching, comparing, and coordinating products while preserving the user's final choice.

Supporting Hypotheses

	Hypothesis
H1	Users begin shopping with inspiration rather than product search.
H2	Users prefer complete outfit recommendations over individual products.
H3	Users value contextual recommendations (occasion, weather, budget) over generic ones.
H4	Users are willing to upload screenshots or describe a look to get personalized recommendations.
H5	Users trust AI-generated recommendations enough to consider purchasing.

Note: “AI can generate outfits” is an implementation challenge, not a product hypothesis — it is deliberately excluded from this list.

Assumption Mapping

Assumption	Importance	Uncertainty
Users struggle to recreate outfits	High	Medium
Users want AI assistance	High	Medium
Users trust AI styling	High	High
Users prefer curated outfits over endless browsing	High	Medium
Users are willing to shop across multiple retailers	Medium	Medium
Users will upload screenshots for recommendations	High	High

The biggest risk isn’t the AI. It’s user behavior — which is exactly why this phase is prioritizing desirability testing before any model or catalog engineering work begins.

12. Desirability Validation Plan (Current Focus)

The goal of this phase is narrow and deliberate: **prove people will change their shopping behavior for curated outfit recommendations before building anything that generates them.**

Method: Wizard of Oz MVP

Instead of building AI, *pretend the AI exists*. Behind the scenes, a human plays Maison.

Flow: 1. User opens Maison (prototype/landing experience). 2. Uploads a screenshot **or** types a prompt (e.g., “*Business casual outfit under ₹5,000 for a client meeting*”). 3. App shows: “*Maison is curating your personalized look...*” 4. Behind the scenes: a human manually assembles Outfit A / B / C using Pinterest, Myntra, Savana, H&M, etc. 5. Recommendations are sent back to the participant.

Why this works: it isolates the question that actually matters at this stage —

Not “Can AI work?” but “Do users value the outcome enough to change their behavior?”

Experiment Design

- **Participants:** 15–20, ages 20–30
- **Task:** “*You’re attending your best friend’s engagement party. Budget: ₹7,000. Find an outfit.*”

Group	Process	Measures
A — Control	Usual process (Pinterest → Myntra → Google → Instagram → Amazon)	Time, confidence, # apps used
B — Wizard of Oz	Upload screenshot → Maison → manual curated recommendations	Time, confidence, # apps used

What we are validating: Can Maison reduce search effort, decision fatigue, and uncertainty *without reducing satisfaction* — not “is AI amazing.”

Metrics

Metric	Type
Recommendation Acceptance Rate	Primary
Time to choose an outfit	Secondary
Self-reported confidence (1–5)	Secondary
Number of shopping apps opened	Secondary
Satisfaction score	Secondary
Willingness to use Maison again	Secondary

Signals to Watch For

- “*The recommendations are good, but I still prefer browsing*” → the value may not be in outfit generation — reconsider whether this is a shopping app or an occasion-planning tool.
- “*I love the outfits, but I don’t want to upload images*” → image upload shouldn’t be the primary interaction; lean into text prompts.
- High confidence scores + low actual purchase follow-through → the product may be better positioned as a planning/inspiration tool than a transactional one (this affects the business model, not just the UX — see [Section 15](#)).

The point of this experiment is to learn what users actually value, not to confirm the original idea was correct.

13. MVP Scope

Feature Brainstorm → MoSCoW

Must Have (validates the core hypothesis):

Feature	Why
Upload inspiration image	Core input method
Text-based outfit prompt	Covers users without a reference image

Occasion selection	Users think in occasions, not categories
Budget selection	Strong, consistently reported need
AI (Wizard-of-Oz) generates 2–3 complete outfits	Core value proposition
Buy links	Lets users act on recommendations
Rate recommendation	Validates recommendation quality

Should Have: weather-aware recommendations, alternative products if unavailable, multiple aesthetics, brand preferences, save outfits, favorite retailers, “why this outfit?” explanations.

Could Have (roadmap): virtual try-on, AI stylist chat, capsule wardrobe, packing assistant, closet management, outfit calendar, wishlist, price tracking.

Won't Have (V1): social feed, influencer marketplace, community forums, live shopping, rewards/loyalty, AR mirrors, fashion blogging.

RICE Prioritization (sample scoring — to be refined post-research)

Feature	Reach	Impact	Confidence	Effort	RICE
Occasion Selection	9	2	95%	1	17.10
Budget Filter	9	2	90%	1	16.20
Recommendation Rating	8	2	95%	1	15.20
Upload Image	9	3	90%	2	12.15
Text Prompt	8	3	95%	2	11.40
Buy Links	8	2	90%	2	7.20
AI Outfit Generation	10	3	70%	5	4.20

AI Outfit Generation scores lowest on RICE (high effort, high uncertainty) but stays in scope because it's strategically essential — a defensible talking point: effort and strategic necessity aren't the same axis.

Rate Recommendation

```

Redefining “Minimum”

Since this is a Wizard-of-Oz MVP, the *minimum lovable product* is not “AI outfit generation.” It’s:

Receive three curated outfit recommendations that feel personalized enough for users to trust and act upon.

Whether a human or a model produces them is invisible to the user during this validation stage — which keeps the test laser-focused on the real question: **will users trust curated recommendations enough to change how they shop?**

14. North Star Metric

Candidate	Rating	Why
Number of outfits generated	☆☆	Measures activity, not value
Average Order Value	☆☆☆	Good for the business, weak signal for the user
Time to Complete an Outfit	★★★★	Captures efficiency
Outfit Completion Rate	★★★★	Measures whether users actually reach a full look
Decision Confidence Score	★★★★★	Directly tied to the product promise

Chosen North Star: *Decision Confidence Score* — after each outfit choice, ask “How confident do you feel about this outfit? (1–5).” The product should drive this up while driving time-to-decision down.

Open question carried into the PRD: *self-reported confidence is a leading indicator but is noisy and doesn’t guarantee revenue or retention on its own. It should be paired with a behavioral/lagging metric (e.g., % of sessions ending in a completed purchase) rather than used in isolation.*

15. Known Risks & Open Questions

These are flagged here deliberately — desirability is being validated first *because* several of these are unresolved, not despite it.

Risk	Potential Impact	Mitigation Direction
Monetization vs. positioning conflict — “retailer-agnostic, cheapest-option” promise is in tension with affiliate-commission monetization	Undermines the core trust proposition if unresolved	Needs explicit resolution in the PRD/business model section before scaling past validation
Catalog/data access — multi-retailer live inventory, pricing, and size data is hard to obtain, especially from retailers who see Maison as competitive	Could make “multi-retailer” promise infeasible at scale	Start with affiliate network feeds and a small set of partnered retailers rather than the full open market
Retailers launch similar features	Reduced differentiation	Focus on retailer-agnostic personalization and wardrobe intelligence as the durable moat
Cold-start personalization	Lower recommendation quality early on	Lightweight onboarding + inspiration uploads to bootstrap signal
AI recommendation errors (post-validation)	Loss of trust	Explain recommendations, collect structured feedback
Low purchase frequency	Lower retention	Expand into wardrobe planning, packing, style history over time
Platform/timing risk — general-purpose agentic shopping (large AI assistants, Pinterest’s own shoppable/visual search) could absorb this wedge	Could shrink the defensible window	Depth in fashion-specific context (occasion, styling logic, wardrobe) vs. general-purpose breadth
IP/copyright exposure — ingesting screenshots of others’ outfits (often celebrities/influencers) to source purchasable items	Legal ambiguity at scale	Flag explicitly in PRD; consult before scaling beyond a research/validation context

Wizard-of-Oz caveat: this test validates *demand* for curated recommendations. It does **not** validate that AI + multi-retailer catalog access is feasible at scale — that is a separate, later-stage feasibility question and should not be conflated with a successful desirability result.

16. What's Next

This document covers **discovery and desirability**. The next phase (tracked separately in the PRD) will cover:

- Business model & monetization mechanics (and resolving the retailer-agnostic vs. commission tension)
 - Feasibility: catalog/data sourcing strategy, AI recommendation approach
 - Viability: unit economics, go-to-market, retailer partnerships
 - Detailed functional/technical requirements for the MVP build
-

This document is a living artifact and will be updated as real user research replaces the simulated research in Section 9.
